BLOCK CHAIN

INTRODUCTION TO BLOCKCHAIN:

“**Block chain**”, the record-keeping technology behind bit coin, is a distributed, decentralized, public ledger.

Digital information (the “block”) is stored in a public database (the “chain”).

“**Blocks**” have three parts:

1. Blocks store information about transactions.
2. Blocks store information about who is participating in transactions. Instead of using your actual name, your purchase is recorded using a unique “**digital signature**”.
3. Blocks store information that distinguishes them from other blocks. Each block stores a unique code called a “**hash**” that allows us to tell it apart from every other block.

How Block chain Works

In order for a block to be added to the block chain, however, four things must happen:

1. A transaction must occur.
2. That transaction must be verified. With block chain, that job is left up to a network of computers. These networks often consist of thousands computers spread across the globe.
3. That transaction must be stored in a block. The transaction’s dollar amount, your digital signature, is all stored in a block. (There can be thousands of blocks).
4. That block must be given a **hash**, a unique, identifying code. The block is also given the hash of the most recent block added to the block chain. Once hashed, the block can be added to the block chain.

Each computer in the block chain network has its own copy of the block chain, which means that there are thousands, or in the case of Bit coin, millions of copies of the same block chain. Although each copy of the block chain is identical, a hacker would need to manipulate every copy of the block chain on the network.

Is Block chain Secure?

They are always added to the “**end**” of the block chain.

After a block has been added to the end of the block chain, it is very difficult to go back and alter the contents of the block, because each block contains its own hash, along with the hash of the block before it.

In order to change a single block, then, a hacker would need to change every single block after it on the block chain.

To address the issue of trust, block chain networks have implemented tests for computers that want to join and add blocks to the chain, called “**consensus models**”, whose odds of being solved are about 1 in 5.8 Trillion!!!!

Why BLOCKCHAIN?
